

EERO AF HEURLIN

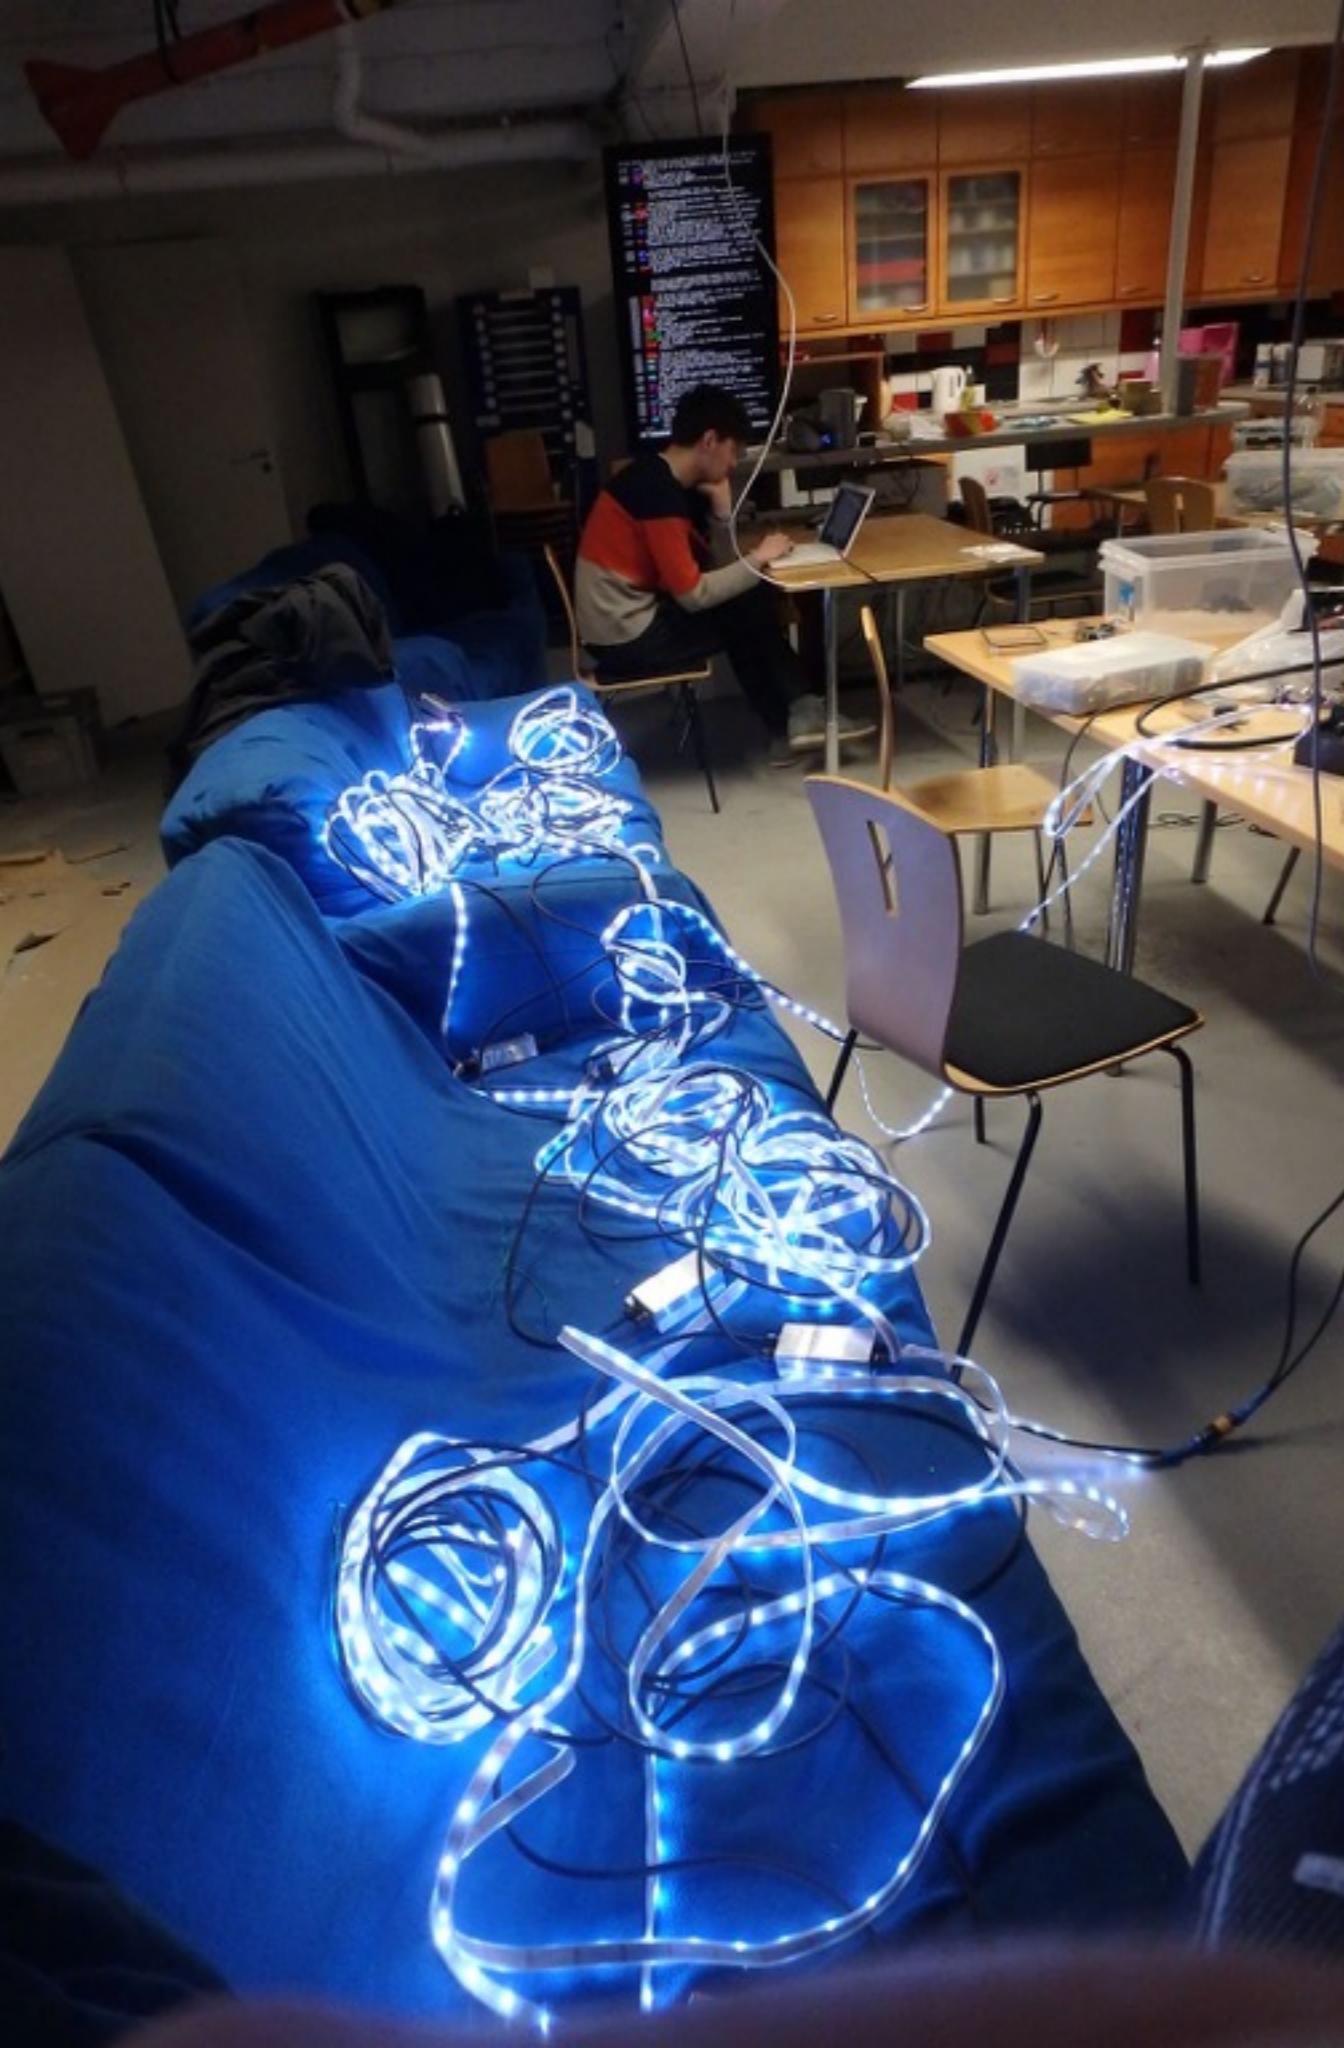

RGB EFFECTS ON LONG LED STRIPS WITH NUMPY AND RASPBERRYPI

YOURS TRULY

Electronics hobbyist since childhood
Active in Finlands hackerspace scene
Currently working at <http://anders.fi>
Believer: Open Source & Open Hardware
<https://github.com/rambo>
<http://fi.linkedin.com/in/eeroafheurlin/>

SOME SPECS

- $50\text{m} \times 30\text{LEDs/m} = 1500\text{LEDs}$
RGB
- in 5m strips using APA102 superLEDs with integrated controller
- SPI-like control protocol
- 5V working voltage (a problem with long strips)
- 10 point-of-load regulators with custom milled cases

PROJECT BACKGROUND

ARTISTS' RENDITION OF THE WALK TO HACKLAB DOOR DURING AUTUMN

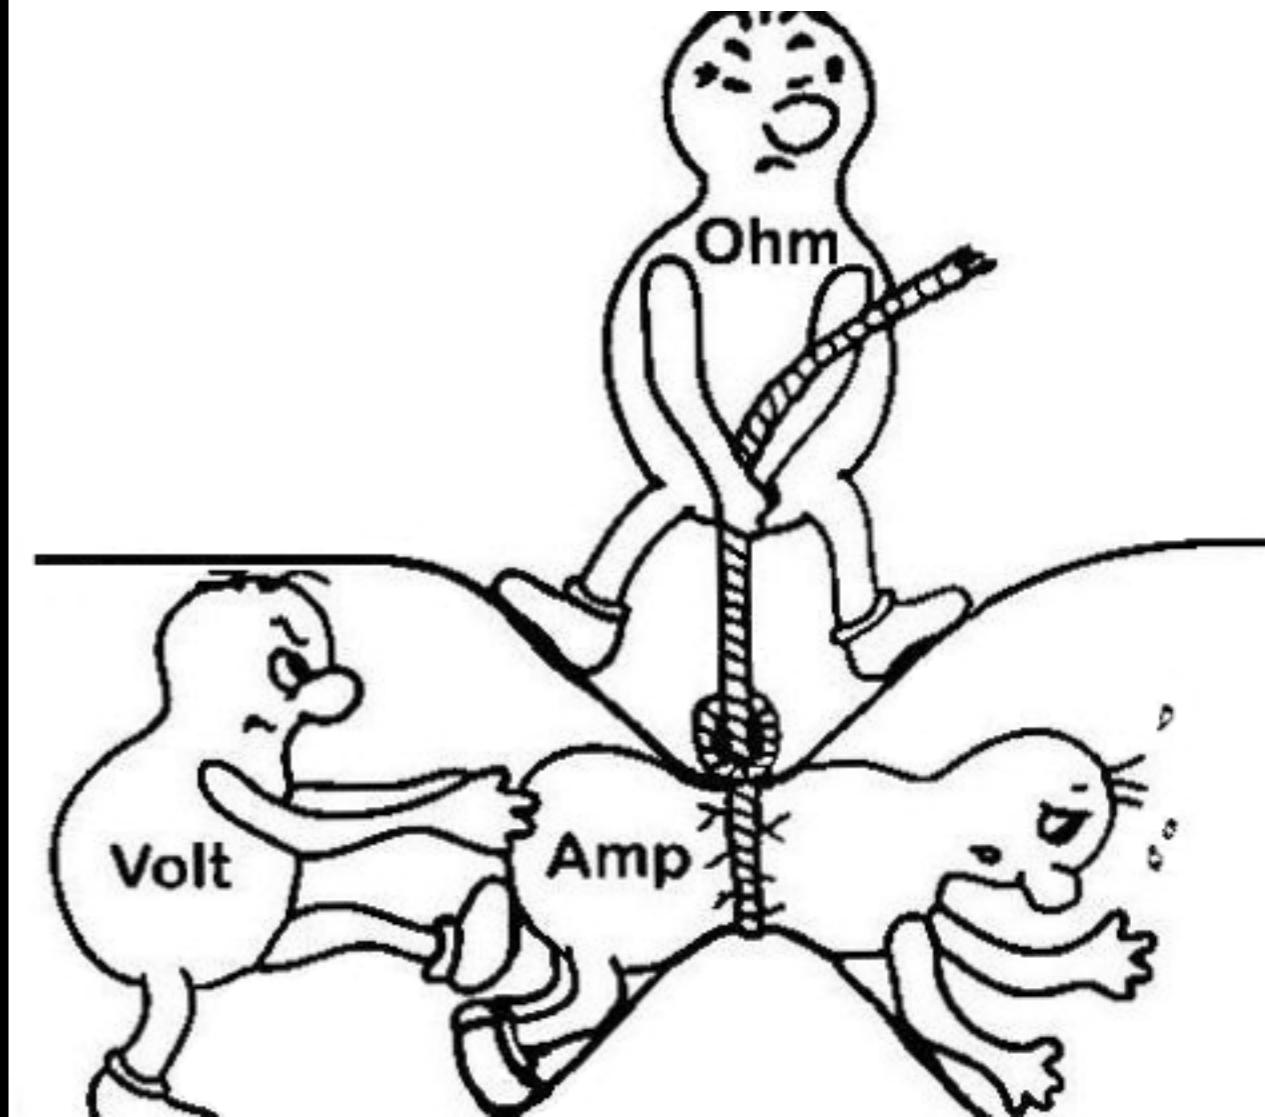

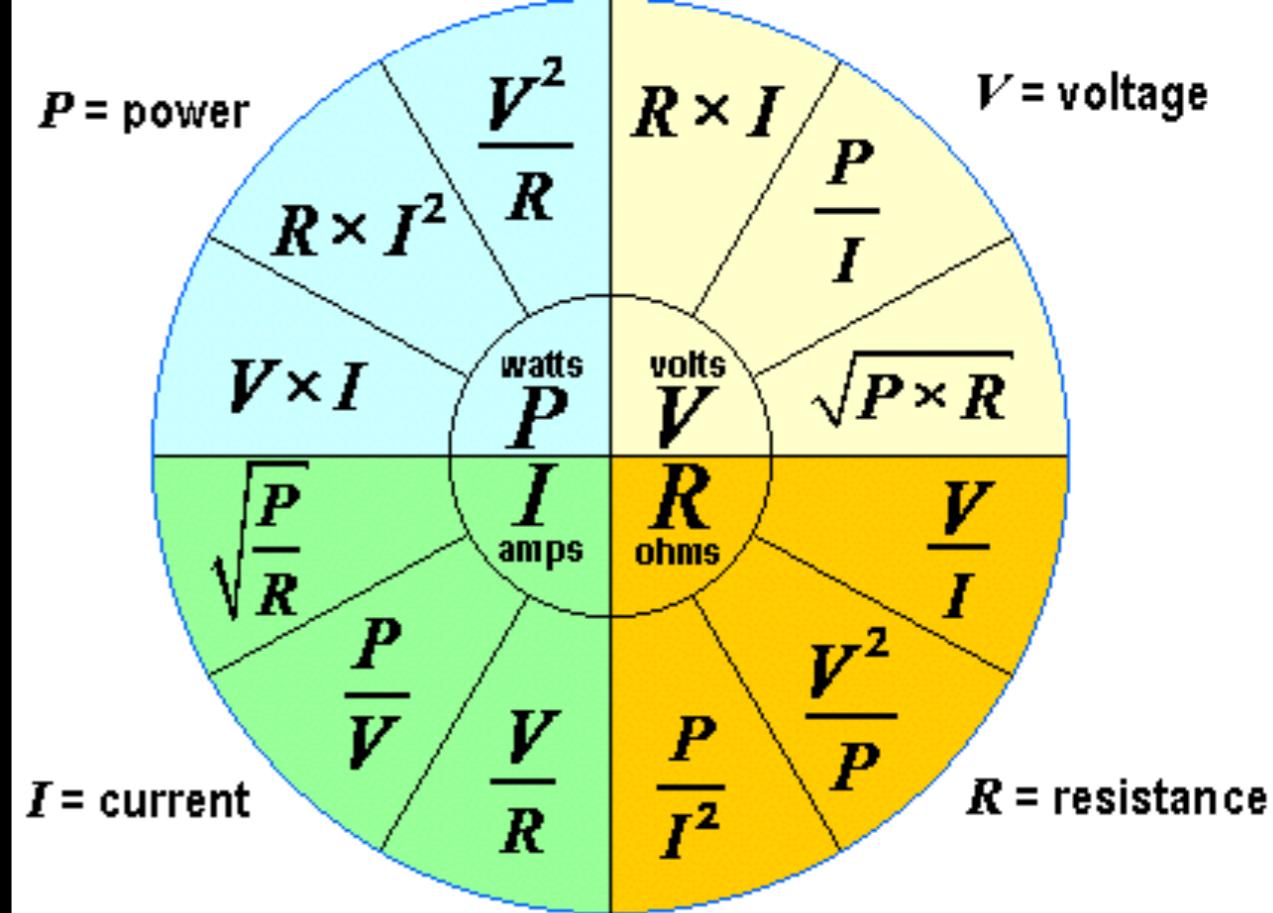

FINDING THE LED STRIPS

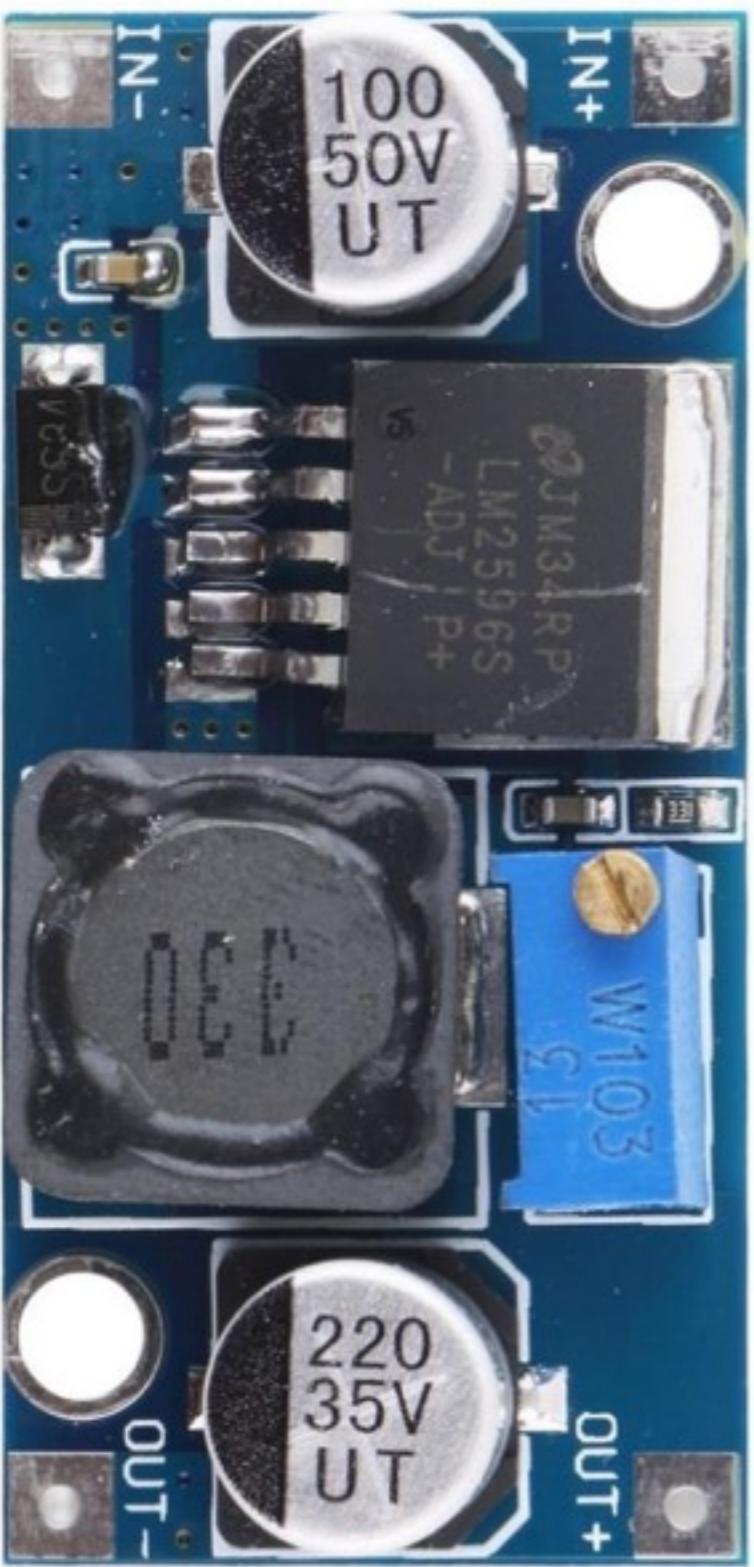

- WS2812 is no-go, the one-wire control protocol is really fiddly with timing and very sensitive to electrical noise
- APA102 is the new hotness, a bit expensive though.
- Alibaba to the rescue.
- After shipping and taxes ~400EUR for 10 * 5m reels.

ELECTRONICS INTERLUDE

- $P = U * I$ and $I = U / R$
- 5V is not a good voltage to deliver significant power
- At full brightness each led takes about 30-40mA -> 45A for 1500 LEDs
- Still "only" 225W of power
- Add point-of-load regulators every 5m fed with 24V -> ~10A for 225W

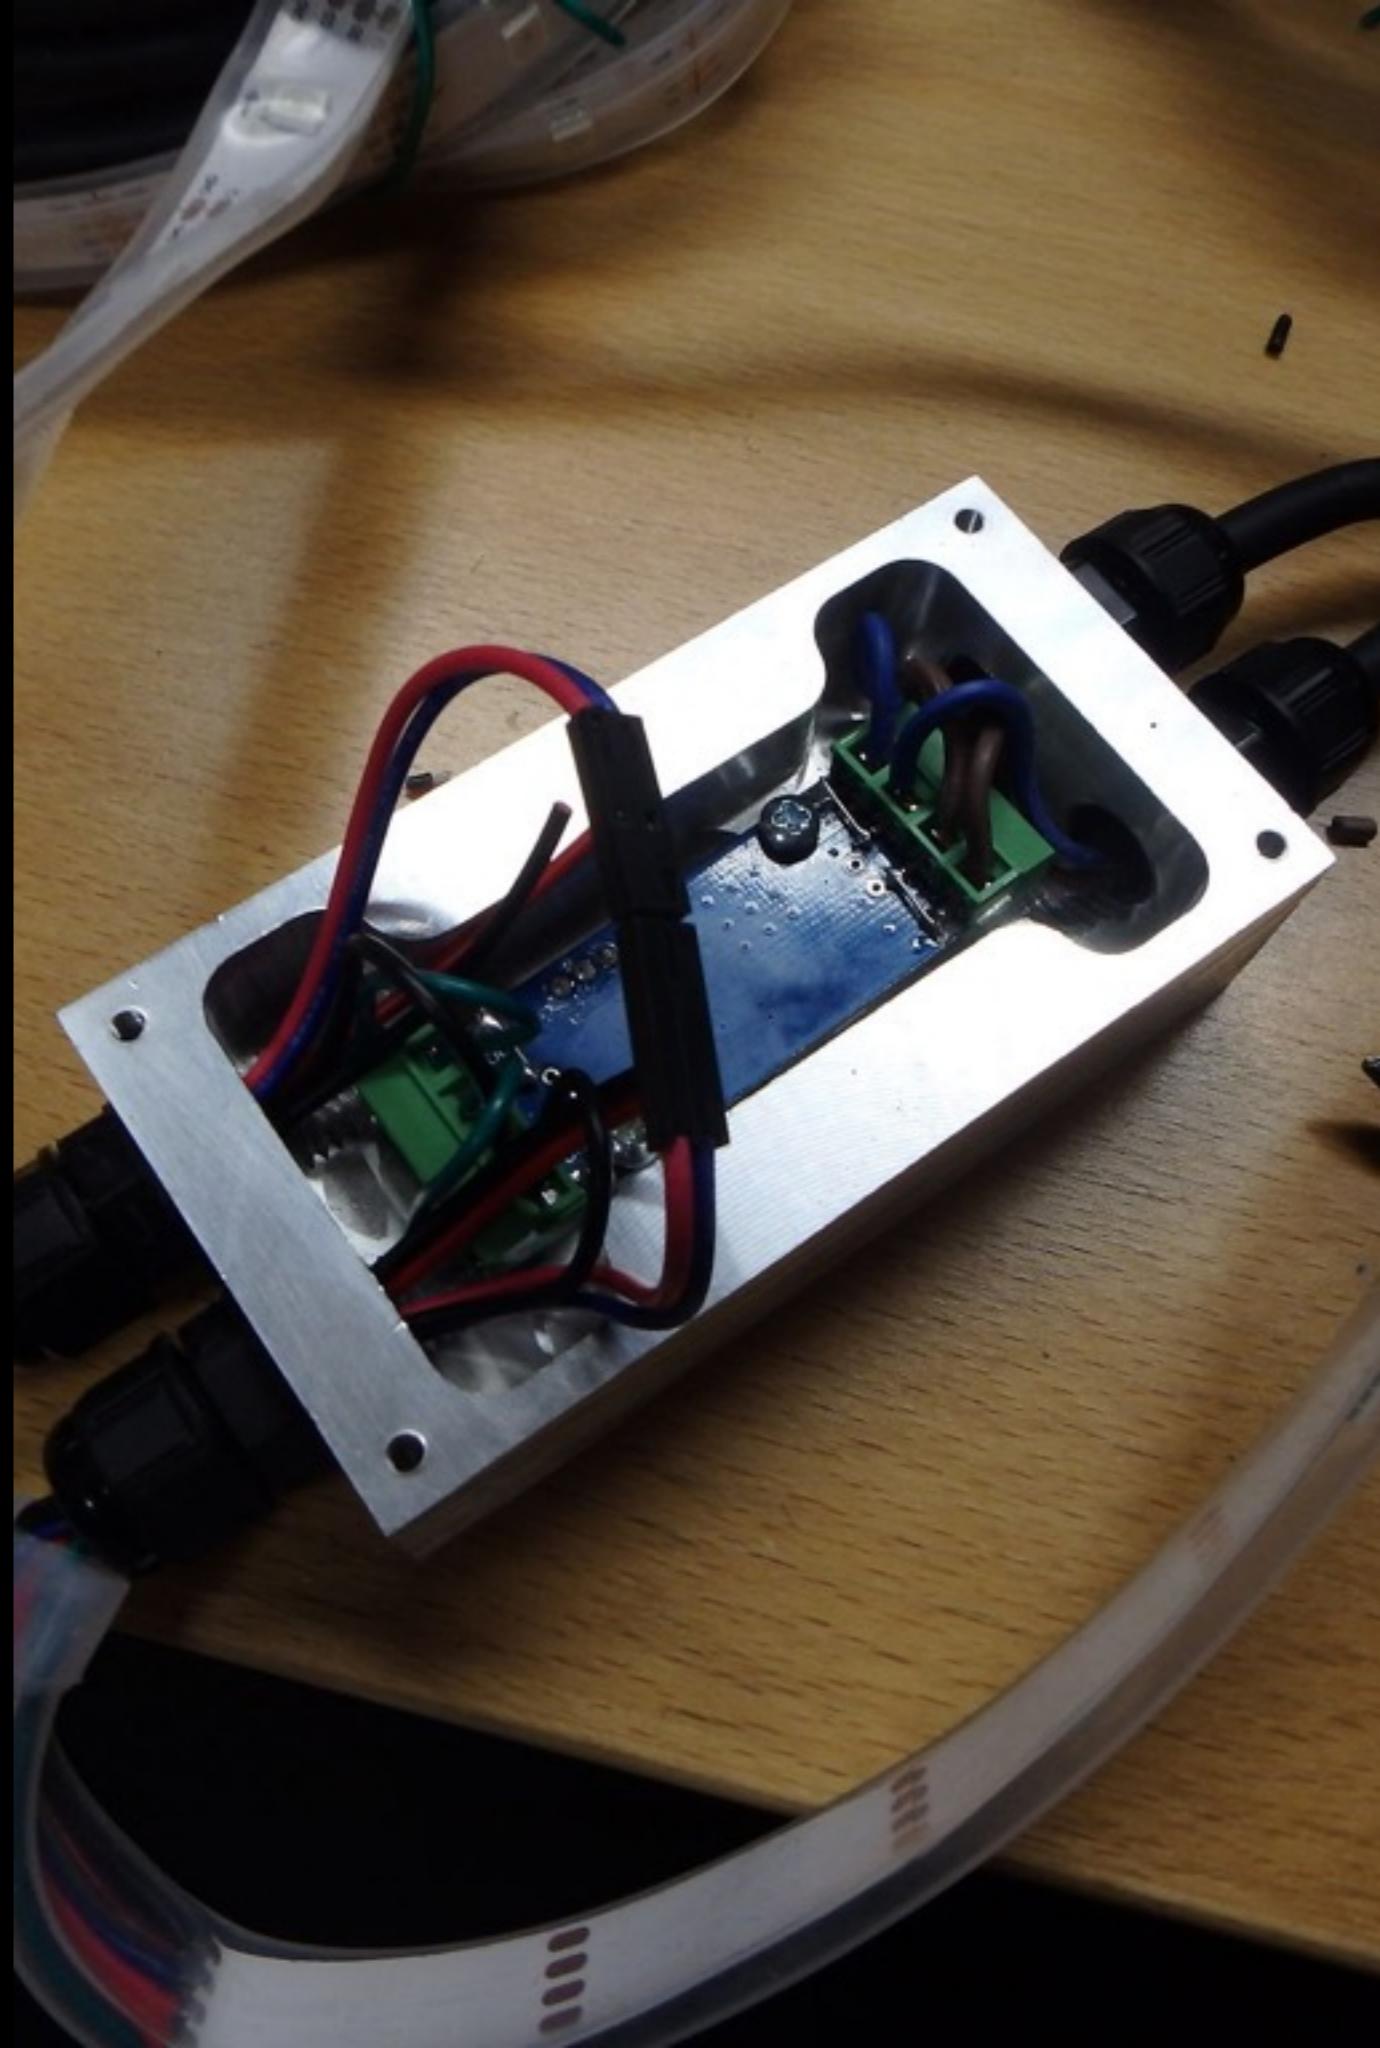

THE REGULATORS

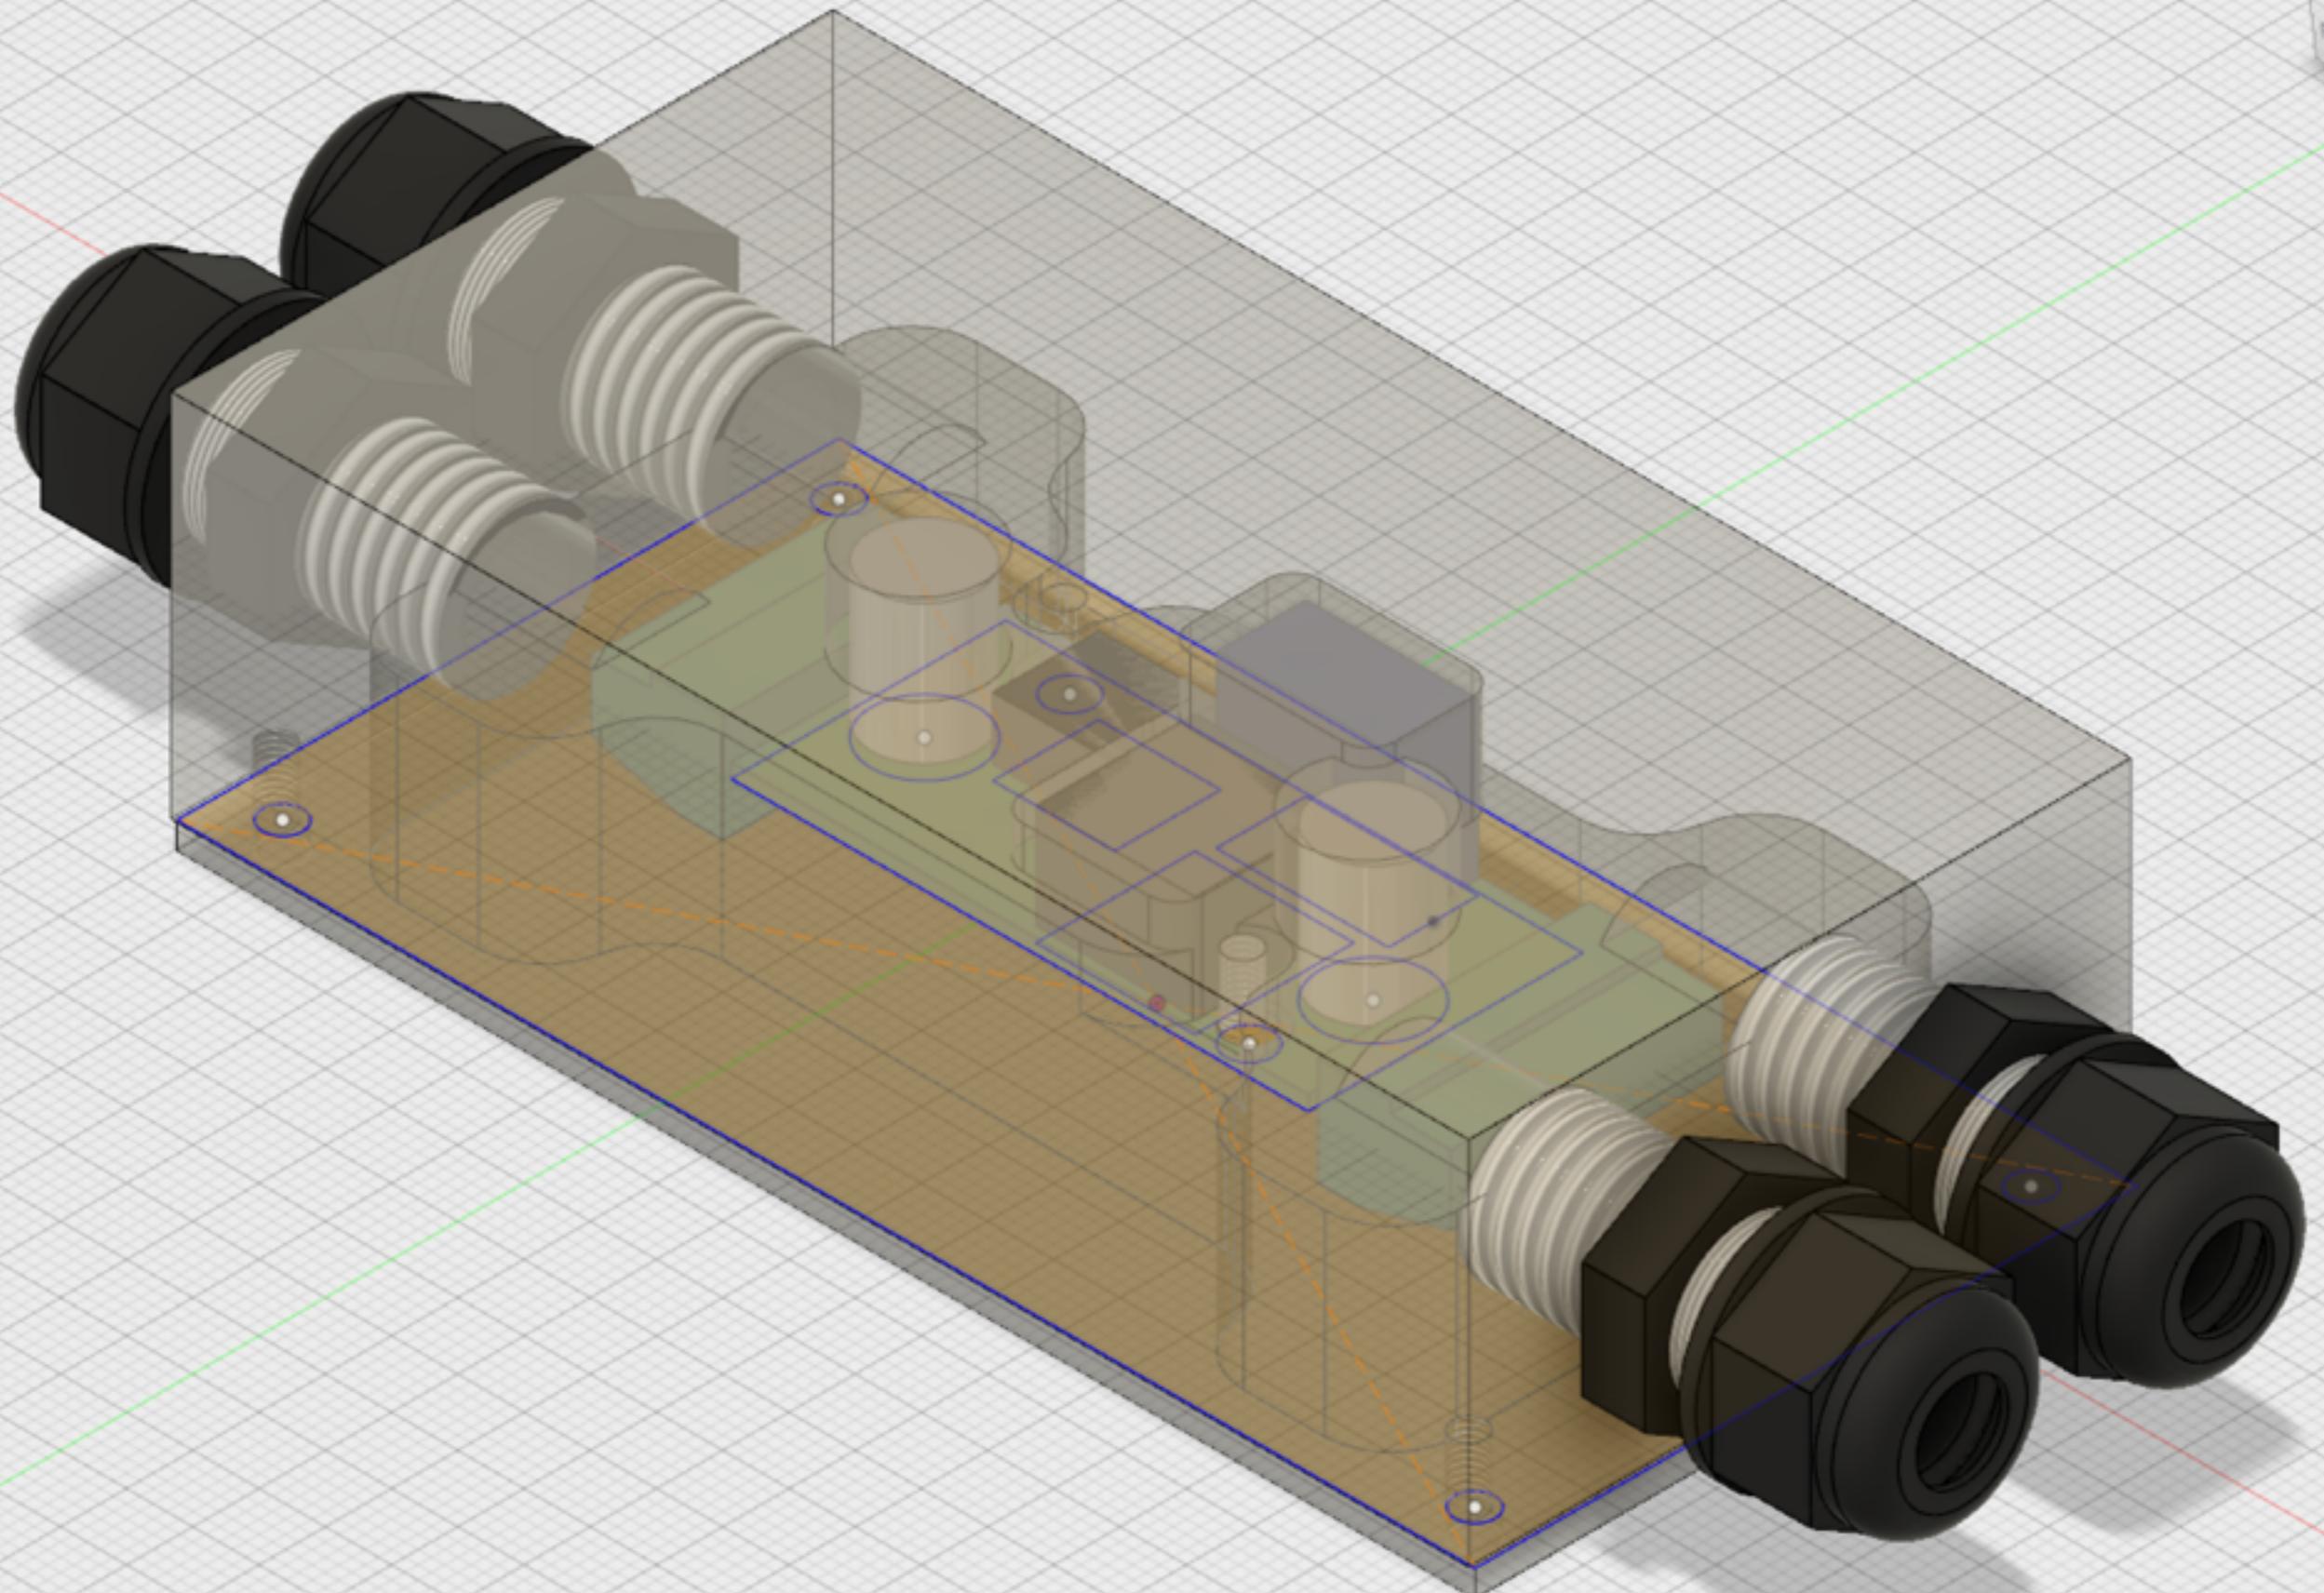

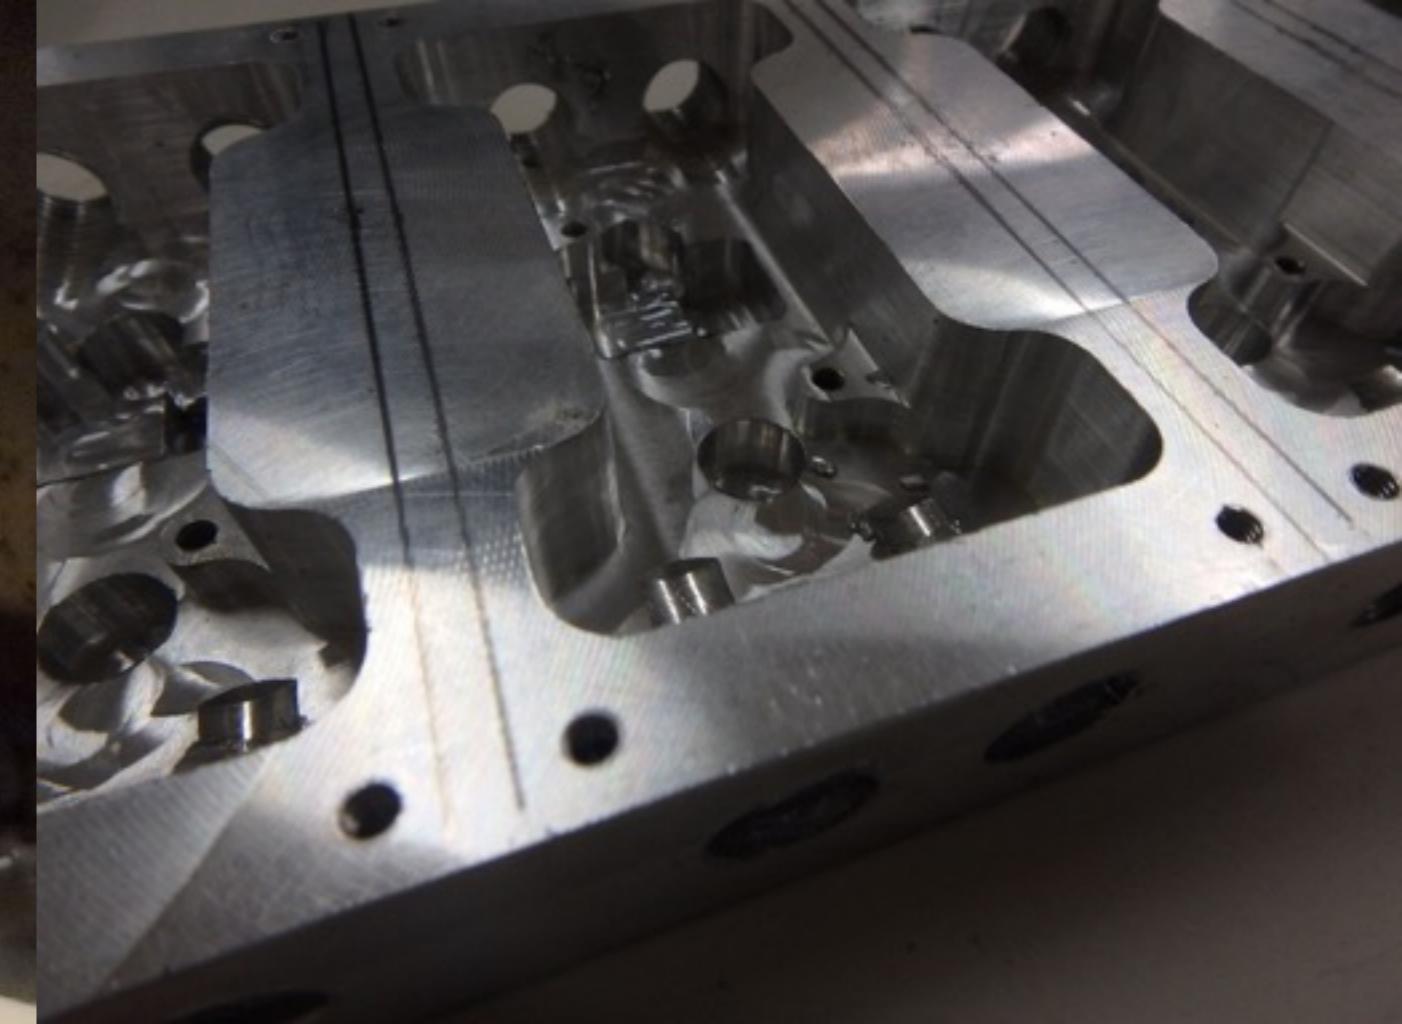

- This design (and a tens of small variations) is small, ubiquitous and cheap
- Had some in my own stock, got a lot more from Aliexpress
- Rated for 2A, some do not reach even that
- Total price maybe 10EUR
- Calibrated output on all to 5.0xxV under load with my HP6632Bs

CASES

- Waterproof
- Acts as heatsink
- Designed in Fusion360
- Used 3D printed versions to test for parts fit
- Using cheap cable glands, proper connectors would have cost a fortune.

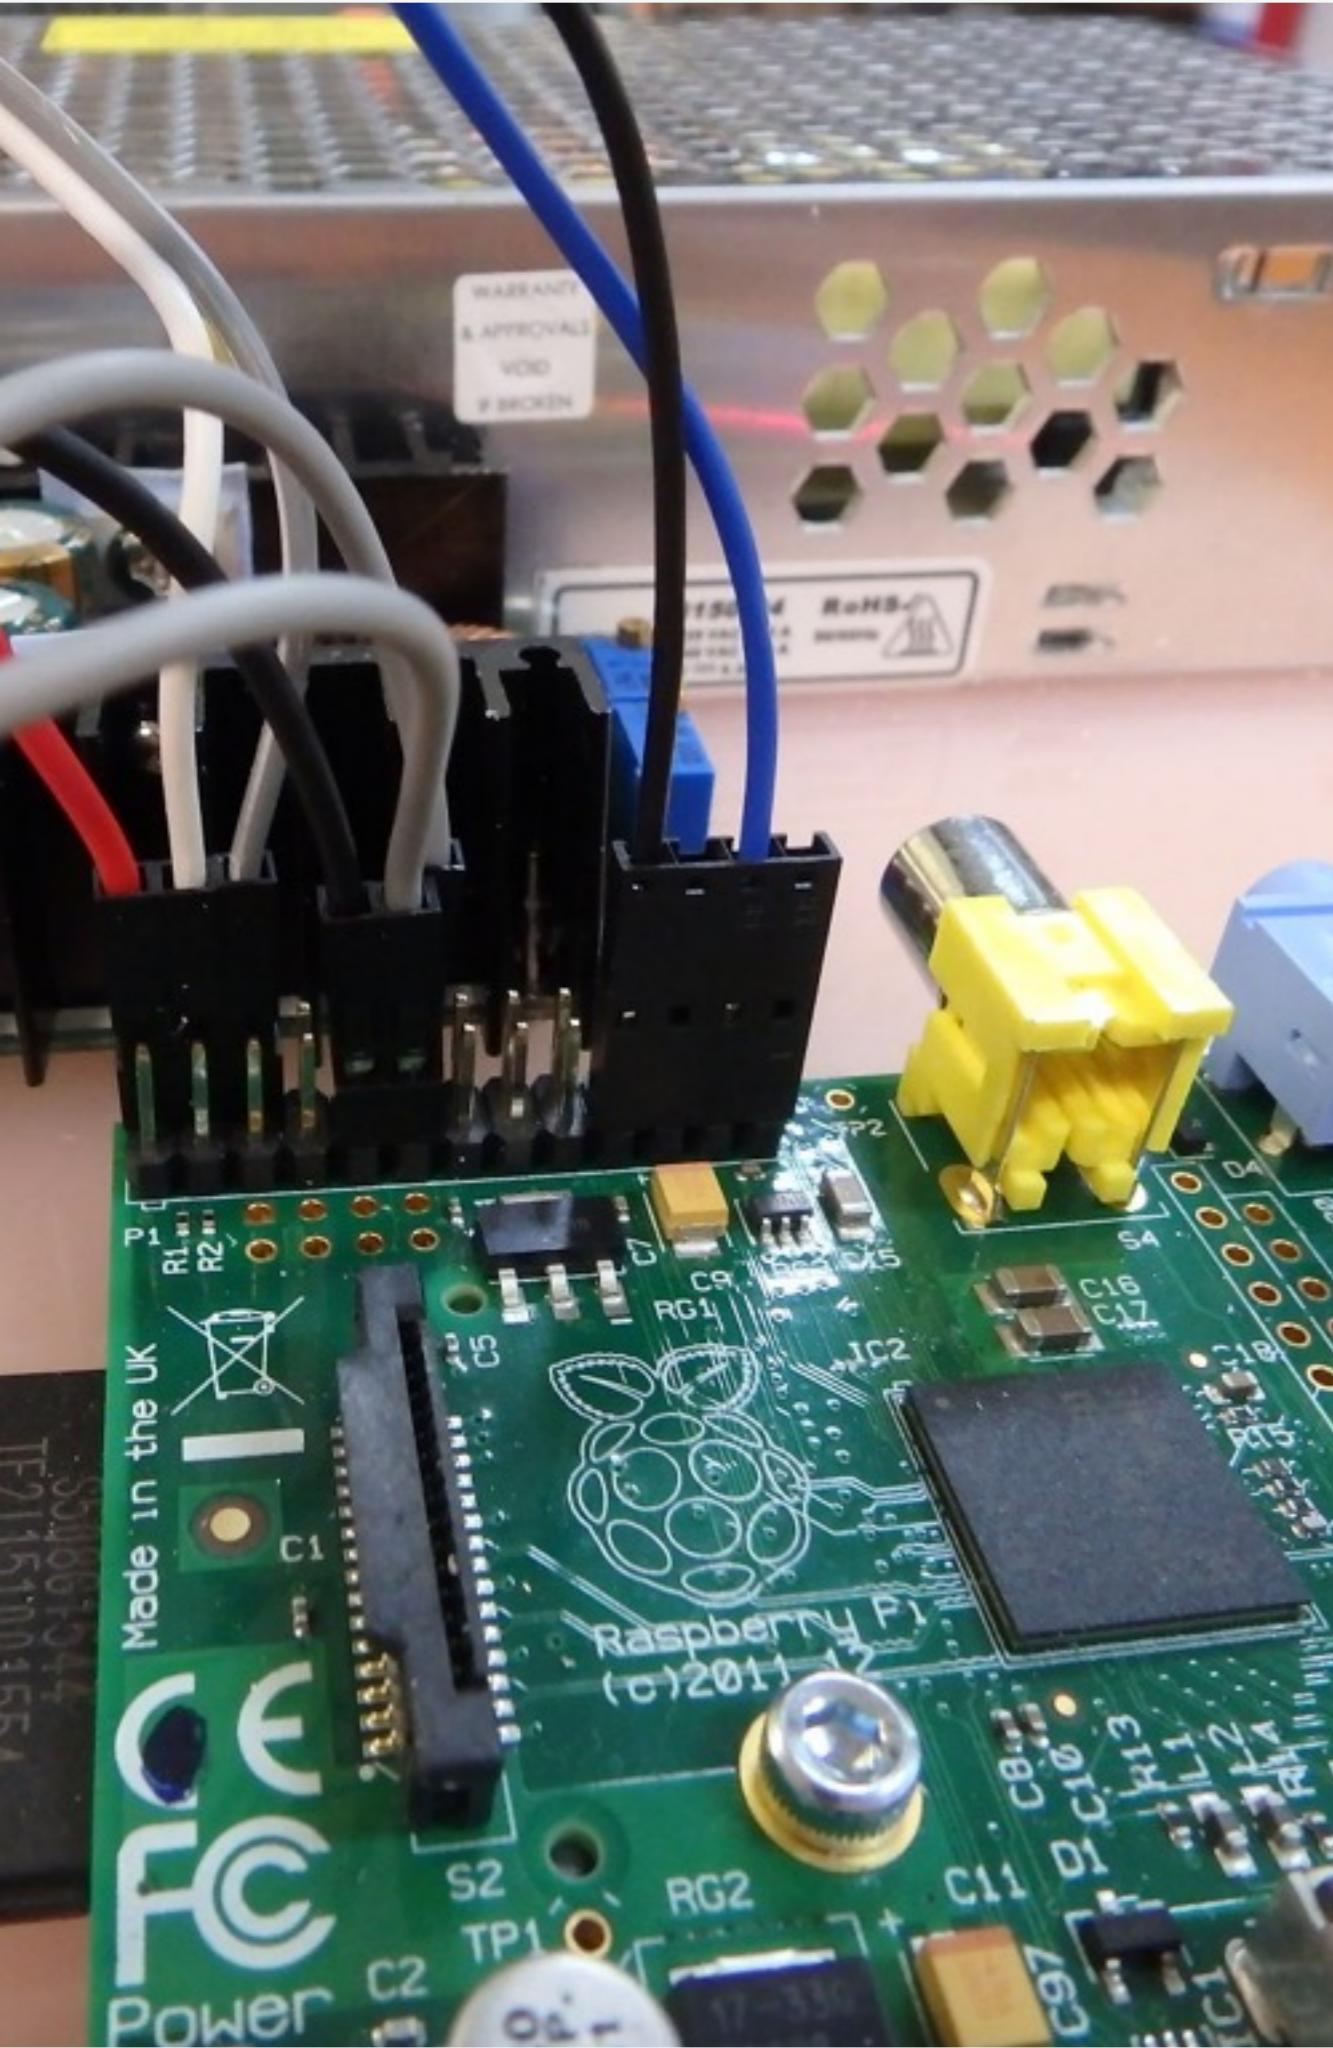

TOP
FRONT
RIGHT

OH YEAH, PYTHON...

GETTING SPI OUT

- RPi has usable SPI hardware
- Libraries “problematic”
- Wrote a ZMQ<->SPI bridge in C (a while back)
- But default kernel settings do not allow over 4k SPI buffer, we send over 6k...

FIRST IMPLEMENTATION

- Very simple effect
- Naive
- Pure Python
- Way too slow on the RPi

```
# -*- coding: utf-8 -*-
from __future__ import print_function
import math
from utils import rgb_floats2bytes

def colors2frame(colors):
    """The colors param is array chrome
    # start frame
    frame = bytearray([0x0, 0x0, 0x0,
    # Leds
    for color in colors:
        frame.append(0xff) # we do not care about the order
        rgbbytes = color.rgb256
        frame.append(rgbbytes[2])
        frame.append(rgbbytes[1])
        frame.append(rgbbytes[0])
    # End frame
    eofbits = len(colors) / 2.0
    eof = bytearray([0xff] * int(math.ceil(eofbits)))
    return frame + eof
```

```

def recalculate_chase_mix(self):
    self.chasepattern = np.zeros([1 + self._tailsize, 4], np.uint8)
    # TODO: Gamma-correct ??
    rgbbbytes = self._chasecolor.rgb256
    self.chasepattern[-1] = [0xff, rgbbbytes[2], rgbbbytes[1], rgbbbytes[0]]
    for x in range(self._tailsize):
        tailcolor = chroma.Color(self._chasecolor)
        tailcolor.alpha = 1.0 / self._tailsize * x
        blended = self._basecolor + tailcolor
        rgbbbytes = blended.rgb256
        self.chasepattern[x] = [0xff, rgbbbytes[2], rgbbbytes[1], rgbbbytes[0]]

@property
def numleds(self):
    return self._numleds

@numleds.setter
def numleds(self, value):
    self._numleds = value
    self.pattern = np.zeros([value, 4], np.uint8)
    self.initialize_frame()

def initialize_frame(self):
    eofbits = self._numleds / 2.0
    eofbytes = int(math.ceil(eofbits / 8.0))
    self.frame = np.zeros(self.pattern.size + APA102_FRAME_START_SIZE + eofbytes, np.uint8)
    self.frame[-eofbytes:] = 0xff

def next(self):
    return self.__next__()

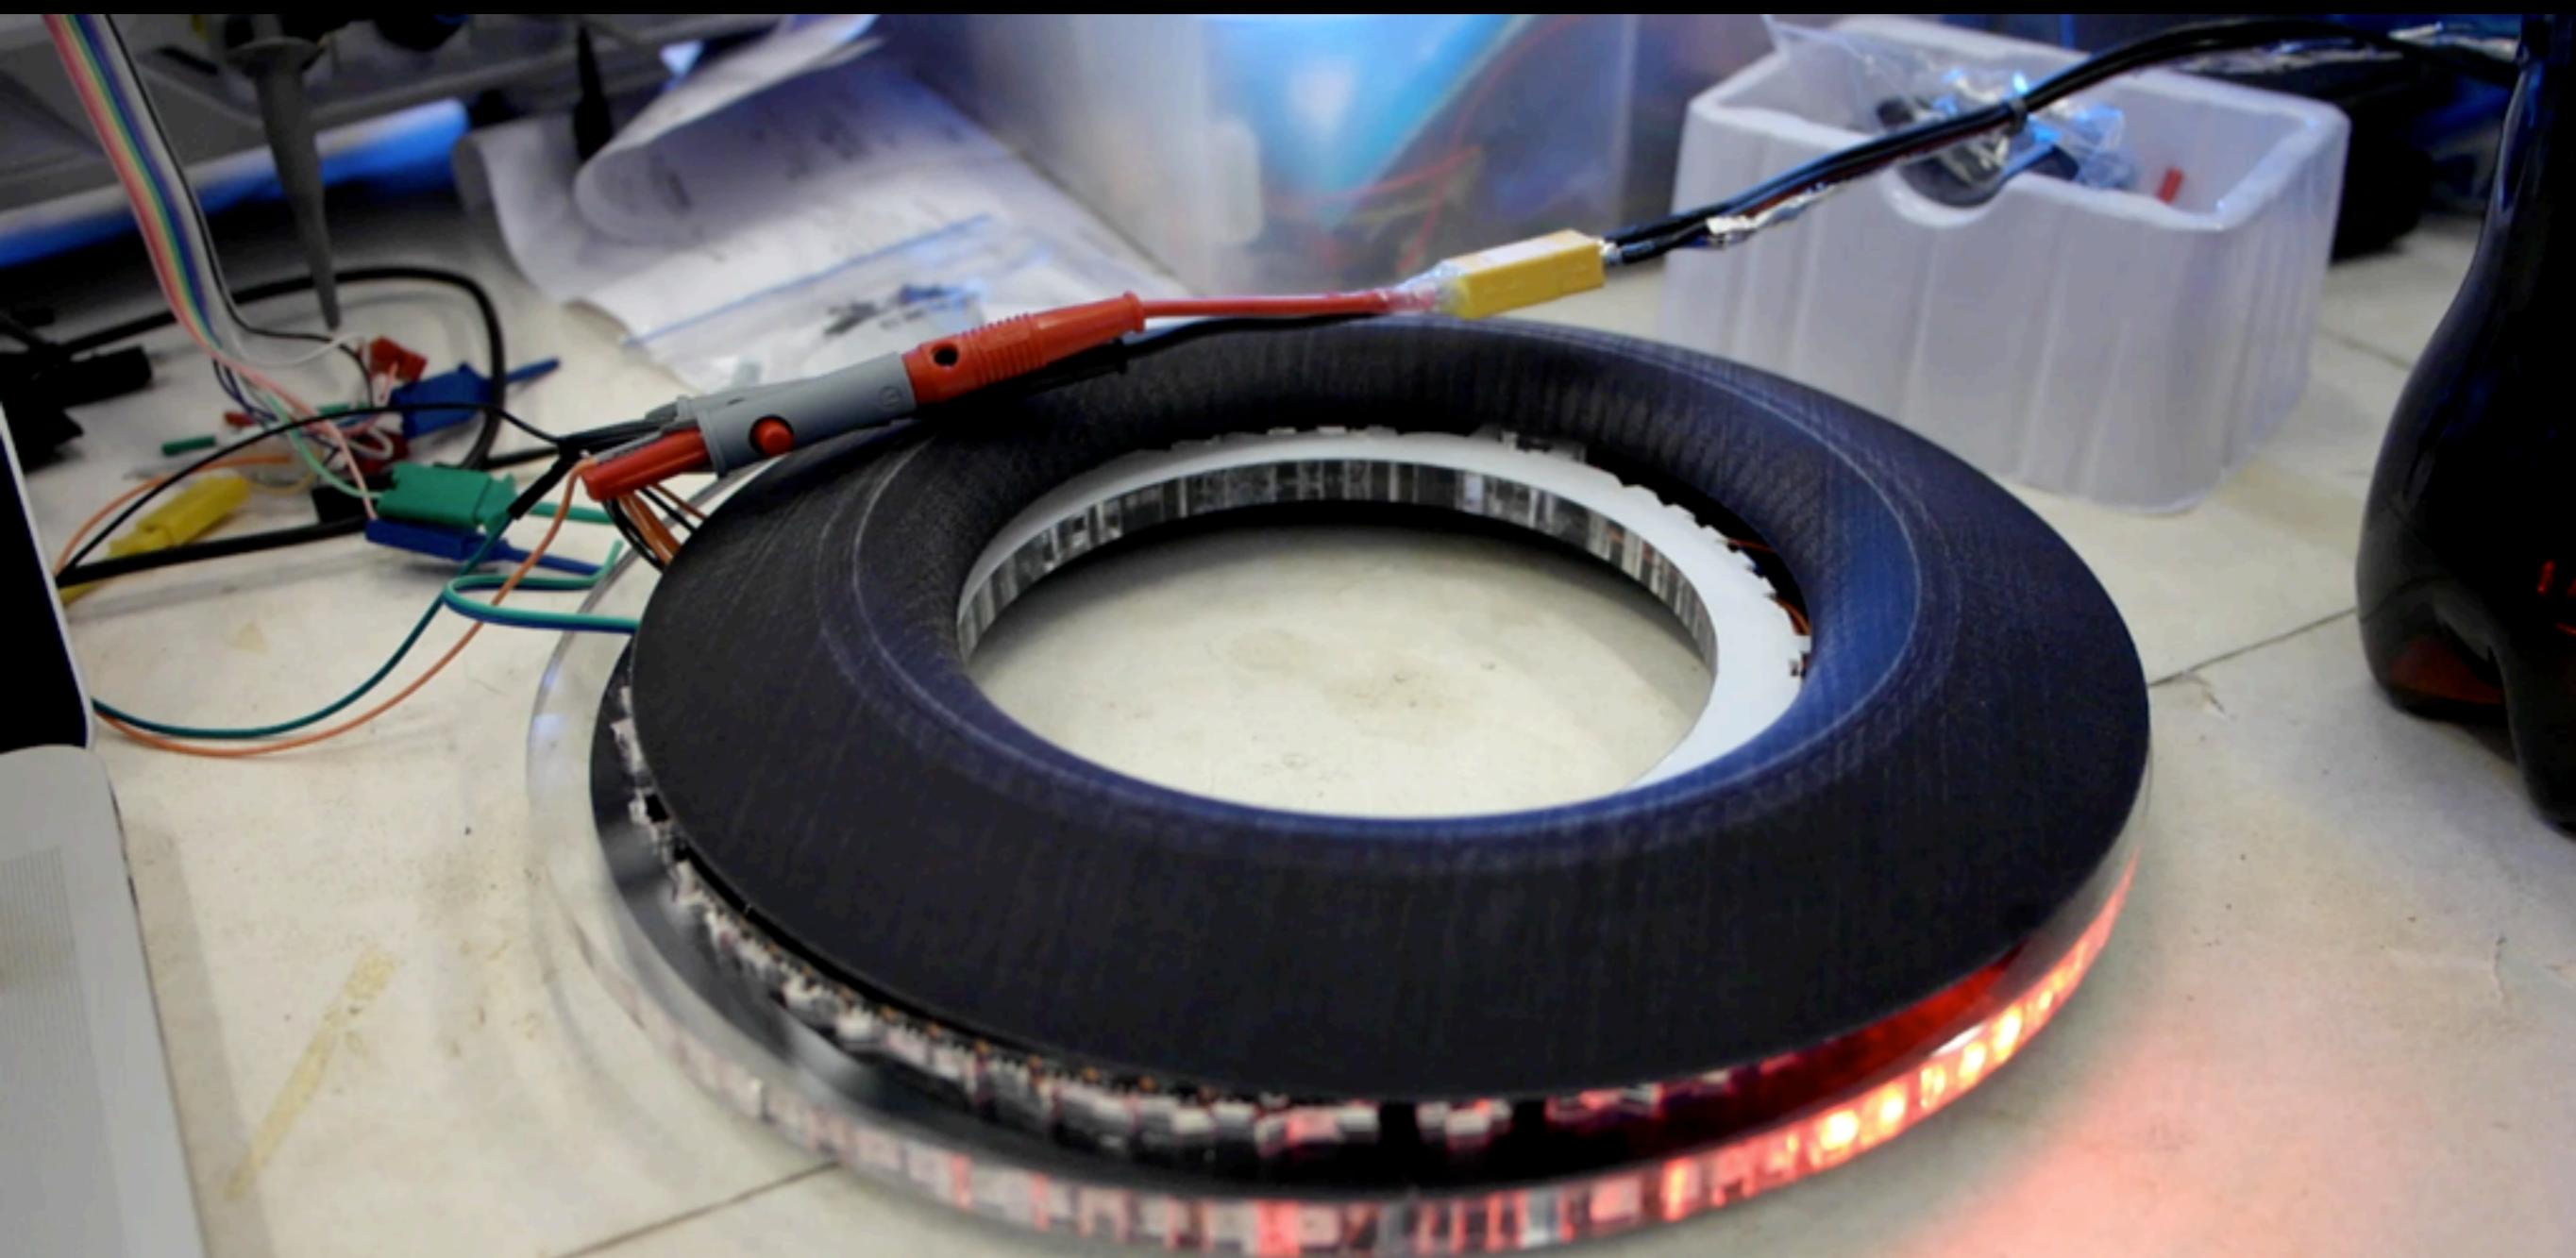

def __position_single_tail(self, chasepos):
    # TODO make this case work too.
    if chasepos < 0:
        return
    tailend = chasepos - len(self.chasepattern)
    # TODO: Gamma-correct ??
    rgbbbytes = self._basecolor.rgb256
    self.pattern[tailend - 1] = [0xff, rgbbbytes[2], rgbbbytes[1], rgbbbytes[0]]
    if tailend < 0:
        self.pattern[tailend:] = self.chasepattern[0:abs(tailend)]
        self.pattern[0:chasepos] = self.chasepattern[abs(tailend):]
    else:
        self.pattern[tailend:chasepos] = self.chasepattern

def __next__(self):
    chasepos = self.i % (self._numleds - 1)
    for x in range(self._numtails):
        self.__position_single_tail((chasepos + x * self._tailinterval) % (self._numleds

```

GO NUMPY

- Use NumPy arrays instead of list
- Use partial array updates
- Use NumPy vector operations
- Pre-calculate color mixing

“You mentioned a simulator”

-MEMBER OF THE AUDIENCE

Simulating 150 LEDs

The screenshot shows two terminal windows side-by-side. The left terminal window, titled 'Simulating 150 LEDs', displays the contents of a directory named 'ledchaser/simulator'. It lists several files: chasegenerator.py, play.py, setup.cfg, chasegenerator.pyc, README.md, simulator, devel-requirements.txt, requirements.txt, and start.sh. The user runs 'cat start.sh' which contains a shell script. This script uses 'source /root/.virtualenvs/ledchaser-34/bin/activate' to activate a virtual environment, changes to the '/usr/src/ledchaser' directory, runs 'nohup python play.py ipc:///tmp/zmqspi 1500 6 &', and then exits with 'd: command not found'. The right terminal window, also titled 'Simulating 150 LEDs', shows the user navigating to the 'ledchaser' directory and running 'workon led'. They then run 'ls' to see the contents of the 'simulator' directory, which includes apa102parse.py, apa102parse.pyc, requirements.txt, and simulator.py. Finally, they run './play.py' which starts the simulation.

```
rambo@ubuntu1404dt: ~/ledchaser/simulator
chasegenerator.py      play.py          setup.cfg
chasegenerator.pyc    README.md        simulator
devel-requirements.txt requirements.txt start.sh
rambo@ubuntu1404dt:~/ledchaser$ cat start.sh
#!/bin/bash
source /root/.virtualenvs/ledchaser-34/bin/activate && cd /usr/src/ledchaser/ &
& nohup python play.py ipc:///tmp/zmqspi 1500 6 &
rambo@ubuntu1404dt:~/ledchaser$ d

d: command not found
rambo@ubuntu1404dt:~/ledchaser$
rambo@ubuntu1404dt:~/ledchaser$ cd simulator/
rambo@ubuntu1404dt:~/ledchaser/simulator$ ls
apa102parse.py  apa102parse.pyc  requirements.txt  simulator.py
rambo@ubuntu1404dt:~/ledchaser/simulator$ workon led
ledsim   ledsim-34

chasegenerator.pyc    README.md        simulator
devel-requirements.txt requirements.txt start.sh
(ledsim)rambo@ubuntu1404dt:~/ledchaser$ ./play.py
^C(ledsim)rambo@ubuntu1404dt:~/ledchaser$ vi play.py
(ledsim)rambo@ubuntu1404dt:~/ledchaser$ ./play.py
```

SIMULATOR

- Accepts exact same frame data as is sent to SPI over ZMQ
- My first VPython application
- Doesn't really scale to hundreds of LEDs as-is.

```
lass ledscene(object):

    def __init__(self, numleds, zmqstream, spacing=33, ledradius=15):
        self.numleds = numleds
        self.stream = zmqstream
        self.stream.on_recv_stream(self.frame_recv)

        visual.scene.width = 1500
        visual.scene.height = 80
        visual.scene.autoscale = True
        visual.scene.title = "Simulating %d LEDs" % self.numleds
